AKUT İNME HASTALARINDA HİPERTANSİYONA YAKLAŞIM

Ahmet TAŞ¹

GİRİŞ

İnme, gelişmiş ülkelerde kardiyovasküler hastalıklar ve kanserden sonra en önemli mortalite ve morbidite sebebi olarak gösterilmektedir. Dünya Sağlık Örgütü (WHO) tarafından yapılan tanımlamaya göre vasküler nedenler dışında belirgin bir neden olmaksızın hızla ortaya çıkan 24 saat veya daha uzun süreli serebral fonksiyonlardaki fokal veya global kayba ait belirti ve bulgular inme olarak adlandırılmaktadır (1). İnmeler, oluşum mekanizmalarına göre iskemik (%85) veya hemorajik (%15) olarak iki gruba ayrılır. Her iki grupta da hipertansiyon önemli bir düzeltilebilir risk faktörü olarak karşımıza çıkmaktadır. Hipertansiyon, ofis sistolik kan basıncı (SKB) değerleri ≥ 140 mmHg ve/veya diyastolik kan basıncı (DKB) değerleri ≥ 90 mmHg tanımlanır (2). İnme riski, hipertansif ($KB \geq 140/90$ mmHg) hastalarda hipertansif olmayanlara kıyasla 3- 4 kat; sınırda hipertansiyonu ($KB \geq 130-139/85-89$ mmHg) olanlarda ise 1.5 kat artmıştır (3).

PATOFİZYOLOJİ

Sağlıklı erişkin bireylerde ortalama arteriel kan basıncında 60-150 mmHg arasındaki dalgalanmalar, serebral kan akımında herhangi bir değişikliğe yol açmaz. Serebral kan akımını sabit tutmaya yönelik bu düzenlenmeye beyin otoregülasyonu denir. Beyin otoregülasyonunu sağlayan temel mekanizma ise serebral arteriol duvarındaki düz kas hücrelerinin transmural basınç değişikliklerinden etkilenmesi ve bunun sonucunda kasılıp gevşemesidir (4). Hipertansif hastalarda otore-

devam edilmesine büyük katkı sağlamaktadır. Trombolitik tedavi öncesi ölçülen SKB >185 mmHg ve DKB>110 mmHg ise labetolol 10-20 mg IV başlanmalıdır. Arteryel kan basıncı hedeflenen aralikta (sistolik≤185 ve diyastolik≤110 mmHg) değil ise trombolitik tedavi başlanmamalıdır (38). Tedaviye rağmen SKB 180-230 mmHg veya DKB 105- 120 mmHg arasında seyreden IV labetolol tekrarlayan bolus (max 300 mg) veya infüzyon şeklinde (2-8 mg/dakika) devam edilir. SKB >230 mmHg ve DKB 121-140 mmHg ise labetalol tedavisi dışında nikardipin IV infüzyon (5 mg/saat dozunda başlanıp tansiyon değerine göre max 15 mg/saat olacak şekilde doz ayarlaması yapılır) da uygulanabilir. Bu tedavilere de yanıt alınamaması halinde IV sodyum nitroprussid infüzyonu 0.5 µg/kg/dk dozunda başlanır ve tansiyon değerine göre doz ayarlaması yapılır. DKB ≥140 mmHg ise IV nitroprussid ilk seçenek ilaç olarak değerlendirilir. Akut hemorajik inmeli hastalarda ise kan basıncı yüksek seyrediyorsa ve kan basıncı kontrolü sağlanmak isteniyorsa bunun için ortalama arteryel kan basıncı (MAP) hesaplanmalı ve MAP değeri 130>mmHg olması durumuna IV ajanlar ile antihipertansif tedavi başlanmalıdır. Bu amaçla akut hemorajik inmeli hastalarda IV labetalol, nikardipin, nitrogliserin, esmolol, enalapril gibi ajanlar kullanılabilir.
